The Illusion of Certainty

Grady Campbell—At CMU’s Software Engineering Institute (SEI), Grady Campbell identifies, develops, and transitions improvements in the process and practices of software acquisition and engineering. In the early 1990s, Mr. Campbell was responsible at the Software Productivity Consortium for conceiving and developing the first comprehensive software product line methodology. Subsequently, he was an independent consultant in software product lines and a Visiting Scientist to SEI’s Product Line Practices Initiative. Other highlights in his 40 years of experience include a Naval Research Laboratory Software Cost Reduction project and a project to build an application generation environment based on adaptable software.

Abstract

Acquisition policy and, even more so, acquisition practice today presumes that certainty is key to success, and that uncertainty or delays in achieving certainty regarding user needs or solution approach will necessarily impede progress. This means that when uncertainty arises during an acquisition effort, the natural response is to make decisions that resolve this uncertainty. Uncertainties arise for various reasons, such as poorly understood, conflicting, or changing needs. If, under pressure to maintain progress, an acquisition effort makes decisions to resolve these uncertainties without sufficient information, expertise, or deliberation, they are really only creating an illusion of certainty; in a practical sense, the uncertainty still exists. This artificial certainty then leads to flaws such as insufficient detail concerning specific needs or premature limiting of solution options. A new approach to acquisition is needed that recognizes that hiding uncertainty is detrimental to success. Systematically exposing uncertainties will be beneficial toward making acquisitions more flexible, cost-effective, and responsive to changing needs.

The Requirements Challenge in Acquisition

The purpose of the acquisition system is to acquire products that provide users in an enterprise (e.g., warfighters) with capabilities needed to perform their mission effectively and efficiently. To this end, user needs must be understood in terms of opportunities for improving the enterprise’s operational systems. Based on this understanding, a product must then be conceived/identified, acquired/developed (engineered and manufactured), deployed, and sustained/evolved. As long experience has shown, many challenges arise in trying to determine actual user needs and achieve a satisfactory product that properly addresses those needs. The essence of those challenges is achieving a balance among needed capabilities, enabling technology, cost, and timeliness in providing a product.

The beginning of the acquisition life cycle is the identification of user needs and technology opportunities that suggest the potential for improved capabilities. These needs are progressively refined, elaborated, and reviewed to create specifications of requirements in increasing levels of detail, feeding into efforts that interpret those requirements to create a conformant product. Again, proper understanding of actual needs in sufficient detail to
permit acquisition of a product that meets those needs is a significant challenge, but, further, needs to be met by a product are not static but continue to change. Future sustainability and improvement requires an acquirer and developer of a product to understand not only existing needs and technologies but how those needs and technologies are likely to evolve in the future.

What experience and numerous studies over the years by the Department of Defense, Office of Management and Budget, Government Accountability Office, National Academies, and industry groups, have suggested is that properly determining needs and expressing these as requirements for product acquisition is difficult and prone to inflexibility and error. For example, quoting from the Defense Science Board Report (2009): “Today, ‘requirements’ are used to define capability needs, implying that nothing less than a specified set of criteria is sufficient. Instead, a more prudent answer is to buy the best capability affordable, in the quantity desired, and fielded in as timely a manner as possible.” However, even this opinion fails to fully address how the acquisition approach could be improved so that products would better address both current and future needs. The following discussion proposes the notion that premature decision making, leading to only an illusion of certainty, is a factor in the requirements problem and that a greater awareness and explicit accommodation of uncertainty throughout the acquisition process would be beneficial.

**Understanding the Concept of Requirements**

“Requirements” is a term that everyone understands on an intuitive level but it can specifically mean many different things. In acquisition policy (USD (AT&L), 2008) requirements is used variously to mean:

- Capabilities needed by a community of users (e.g., mission, user, or capability *requirements*)
- Rules that must be followed in performing acquisition activities (e.g., statutory and regulatory *requirements*)
- Criteria against which the acceptability of a product development effort will be evaluated (e.g., program *requirements*)
- A specification of the expected behavior of a product being acquired (e.g., product, operational, or system *requirements*) (i.e., the guidance that product developers are given to know what to build or to describe what has been built)

In a general sense, all of these uses are consistent but the practical implications of each for acquisition differ substantially. In particular, user requirements, program requirements, and system requirements are all different expressions of the single notion that a product is needed that will allow users to perform their mission more effectively. For an acquisition to be successful, all of these expressions must be consistent.

In fact, however, this presents a dilemma: acquisition rules require that an acquisition program can proceed only after its requirements have been approved. Program requirements are derived based on user requirements and are the basis for defining product requirements. With respect to an envisioned or existing product, its requirements can be thought of as a model of the observable behavior that the product must exhibit to provide the capabilities needed by users. If user requirements are inaccurate, this will undermine program and product requirements unless there is a means for modifying them during the course of product development.
What the experience of many people suggests, supported by recurring government and industry studies, is that requirements at any level of detail are often flawed: incomplete, inaccurate, misunderstood, and prone to unforeseen change. The best means we have for mitigating these flaws is systematic iteration through all aspects of product development, allowing for the progressive refinement of a shared understanding of needs, constraints, potential solutions, and tradeoffs. If acquisition policy or practice dictates that requirements at some point early in the acquisition process must be viewed as complete and immutable, it is likely that resulting products will both embody difficult-to-correct flaws and fail to keep up with changing needs.

The acquisition system today seems to encourage, and practitioners conform to, the idea that a proper acquisition depends on achieving certainty, in requirements and in the cascade of subsequent decisions that flow through the acquisition process. What they actually achieve is the appearance of certainty but such certainty can in fact be an illusion built upon premature, inadequately reasoned decisions, inadequate understanding of needs, and failure to account for changing needs, technology, and operational context. Explicit recognition and accommodation of uncertainties is a way around this dilemma that will help programs avoid commonly experienced cost overruns, schedule delays, and product defects, while supporting concerns for proper accountability.

**Causes of Uncertainty in Requirements**

In thinking about the nature of requirements, we can easily identify several potential sources of uncertainty. To properly understand and specify requirements, these need to be exposed, analyzed, and documented with rationale:

- **Incomplete knowledge.** User needs are usually specified by people who are knowledgeable in the mission of the enterprise and how it currently works. However, they often have only limited knowledge of how those needs may be realized in solution products, how different aspects may interact in a solution, or how new solutions could change the way the enterprise works; as a result, they may express needs in ways that unintentionally seem to limit the potential solution. Furthermore, there are usually aspects of user needs about which even experts disagree. Because no one can have complete knowledge of all aspects of any endeavor, it is likely that any description of user needs will mask areas of uncertainty or disagreement. Customers may recognize that this uncertainty exists but, lacking a proper awareness of the need and means to communicate the variety of alternatives that they see, they may instead make a reasoned but ultimately arbitrary choice.

- **Imprecise understanding of needs.** While customers may be competent to define user needs, developers are likely to lack the same depth of understanding. Experts in a field may share assumptions, concepts, and terminology that enable them to describe needs in simpler terms that acquisition agents or developers with less of that expertise may misinterpret. It may not be apparent that developers have a different understanding until a product exists and its behavior can be observed in use. Needs are often better understood after potential solutions have been developed and comparatively evaluated, preferably with exposure to knowledgeable users, leading then to being able to define better requirements.

- **Differing needs among users.** Users doing similar jobs may in fact legitimately not have exactly the same needs. If requirements characterize all users doing
similar jobs as having the same needs, the developer may create a product that
properly meets the needs of only some users. A product that imposes a particular
viewpoint on all such users will make some of those users less effective.

- Changing needs. Needs change over time because of changes in mission,
  operational context, and technology. Defining needs only from the perspective of
  a single point in time ensures that these are inaccurate with respect to other
times. Framing needs as fixed without consideration of potential change over
time imposes uncertainty on what is potentially predictable change that may be
better accommodated by developers if known.

**Why Apparent Certainty in Requirements May Be an Illusion**

By the time a product is deployed, its actual (“as-built”) requirements have been
effectively determined. Still, although in a practical sense there can be no actual
uncertainties about the behavior of a deployed product, there may not be a complete and
accurate specification of what those requirements are. In that sense, there may be no one
who can be certain about all aspects of the product’s behavior.

Although acceptance of a product depends on compliance with acceptance criteria
usually expressed in the form of requirements, the same problem can exist for those: there
may be unacknowledged uncertainties that have been improperly resolved. In a process in
which encountered uncertainties are simply decided away, without proper identification and
systematic analysis of factors and tradeoffs, and not documented with rationale, it is likely
that some uncertainty still exists relative to actual current or future needs. This same
argument applies as the reasoning behind particular requirements is traced back through
acquisition decision making.

Uncertainty can exist at any level of requirements. The fundamental uncertainty is
how does someone determine and communicate what they want or need. That phrase itself
reveals a basic issue: how do we distinguish aspects that we must have from what we might
like to have from what we would accept. The essence of engineering is identifying and
weighing tradeoffs among alternatives but the nature of defining requirements is not only to
make a definitive statement about what a customer needs but in doing that to also eliminate
unsuitable solutions. When this is done without full knowledge of actual possibilities,
potential solutions can be prematurely constrained.

In looking at how requirements are determined, there are many factors that can lead
to the various kinds of uncertainty:

- No individual or collection of people will have complete knowledge of all aspects
  of an existing system and its operational context; requirements are inevitably only
  a partial description that requires particular expertise for correct understanding.

- It is not possible to communicate all that an individual or collection of people
  know about a system or how it might be improved; a complete description of
  what is known would require years to produce and years to consume.

- Among a collection of people, even with similar spans and depths of knowledge
  in an area, there will be disagreements, some that can be resolved and some
  that are fundamental; the conventional answer is to insist on achieving
  agreement, even though the substance of the disagreement may itself provide
  more accurate insight into a correct solution than either individual or consensus
  viewpoint.
- Even if people are able to correctly characterize needs at a point in time, needs as well as enabling technologies change over time; requirements that only describe what is needed currently will be incorrect at other times in the future.

- Both natural language and graphical notations are frequently understood differently by different people, particularly when lacking similar expertise; two examples of gaps in communications are between users and developers and between systems engineers and software engineers.

There are other factors in the nature of requirements that can also lead to uncertainties about the needed product:

- Users typically view their needs in terms of being able to accomplish their job and new or improved capabilities that would enhance this; this view is often constrained by inaccurate assumptions about what is possible and what can and cannot be changed.

- When a product built to address users’ needs is deployed, it often changes the users’ perceptions not only of what their needs are but also of what is possible, leading to their needs “changing” yet again.

- Requirements being only approximate descriptions of needs and constraints on potential solutions may in fact omit information that the customer knows and assumes but that the product developer does not.

- Requirements are frequently not limited to what is absolutely needed but also reflects the customer’s perception of what is desirable without distinguishing between these; this in fact often precludes options that would allow the developer to make better tradeoffs in creating a product that is a best fit to purpose within given cost and schedule constraints.

**Using Uncertainty in Writing Better Requirements**

Parnas and Clements (1986) argue for the ideal of a rational process for the design and building of (software) products. As part of this, they characterize requirements as a definition of the expected observable behavior of a needed product, sufficient to answer developer questions about what is to be built. A way to understand this is to recognize that requirements constitute a model of a needed product. From this perspective, requirements should define the capabilities that a product needs to enable for its users.

However, it is not enough to describe a product at a fixed point in time and with uncertainties hidden. In fact, Parnas and Clements argued that a rational process is not usual practice because of incomplete and inaccurate information in documentation caused by underlying issues in how documents are written (e.g., poorly organized, stream of consciousness exposition, poorly and inconsistently written by multiple authors, dispersed repetition of related or conflicting information, confusing and inconsistent terminology, narrowly conceived). In fact, these problems still exist and are often symptoms of false certainty. Authors must produce requirements that appear certain even if uncertainty has not been properly resolved. No means is given to indicate areas of uncertainty, doubt, or likely change that are left to be resolved.

A common effect of resolving uncertainty with arbitrary decisions is to prematurely limit solution options. Not having a means of specifying requirements so as to permit alternative solutions, the customer may instead resort to describing a particular solution that has worked for similar problems in the past. By hiding the uncertainty and precluding further
analysis, the developer may be forced to adopt the described solution rather than having the
option of developing and evaluating other potentially more appropriate solutions.

A factor in being able to evolve a product as user needs change is the ability to
recover the rationale for why requirements are what they are. Some products today include
obsolete capabilities and are difficult to change simply because no one is sure why the
product does all that it does, why it is built the way it is, and whether any aspects of what it
does are no longer needed by users. A natural by-product of focusing on and explicitly
analyzing uncertainties is that the rationale for the resolution actually chosen will be
documented. By capturing this rationale, we have at least a partial characterization for the
product not only as it finally exists but also as it might have been differently done, giving a
basis from which to revise the product when needs change.

**An Existing Approach for Limited Accommodation of Uncertainty**

Some experience already exists with building products with a focus on uncertainty. When an organization has a need to build multiple products, in support of customers having
similar but not identical needs, a product line approach provides a process for building a set
of similar products from a common base of reusable software, documentation, and test
assets (Campbell, Faulk & Weiss, 1990; Clements & Northrop, 2002). This approach
depends on identifying precisely the ways in which the needed products will be alike
(commonalities) and the ways in which they will differ (variabilities). The techniques for
identifying how products will differ and in resolving those differences to create a specific
product is similar to the model proposed for identifying and resolving requirements
uncertainties in general.

With a product line approach, not all types of uncertainty are addressed but only
those related to customers’ changing or diverse needs. Uncertainties related to potential
changes in customer needs or to needs that differ among customers are systematically
identified and formulated as decisions that will be resolved late in the production of each
specific product in consultation with the individual customer for that product. The ability to
resolve these uncertainties in different ways is systematically engineered as production
options. This provides the means to deliver a customized product to each customer and to
deliver a revised product to each customer as their needs change. Identifying decisions that
encapsulate the implications of diverse and changing customer needs on product
requirements for a set of customized products is integral to the concept of a product line.
This approach also provides the means to rapidly build alternative solutions to particular
customer needs as a means to helping the customer find the best fit to their needs.

**A Strategy for Comprehensively Accommodating Uncertainty**

A recent National Academies study (*Achieving Effective, 2009*) has recommended
that system requirements (“big R”) for IT systems be defined strictly and fixed at the mission
capabilities level and that more detailed requirements (“little r”) continue to be developed
and refined throughout the acquisition process. Consistent with the challenges of
uncertainty, this study advised that requirements evolve progressively through ongoing
interactions with end users and assessments of available technologies. The study alluded to
a recent Joint Capabilities Integration Development System policy that prescribed a similar
approach.
Uncertainty in requirements is not a “problem” to be eliminated. Recognizing and properly exposing uncertainty is an aid to communicating more effectively about needs and potential solutions. Some uncertainties, once recognized as such, can be resolved through an analysis of alternatives and tradeoffs during the development process; others are inherent aspects of the problem being addressed and require different resolutions over time or for different customers. From experience with product lines, there are good techniques for expressing uncertainty which can guide developers in providing needed flexibility with mechanisms for tailoring and product customization to better accommodate the needs of customers over time.

A strategy comprising three elements will give the means to better expose and resolve or accommodate uncertainties in requirements:

- View product development as a process whose ancillary purpose is the elaboration, refinement, and correction of requirements as initially defined.
- Document all differences and their implications when domain experts have differing views on any aspect of requirements.
- For any aspect of requirements for which there are alternatives, that are the subject of tradeoffs, or that may change in the future, document the rationale for its current realization in comparison with identified alternatives.

These elements together are meant both to improve the requirements as a description of the product being acquired and also to provide the basis for revising those requirements as understanding of needs improve or when needs or technology change in the future. When uncertainties exist and are resolved, capturing the rationale provides valuable insight to future developers. When needs change, this rationale provides a basis for understanding the implications of having to differently resolve those previous uncertainties in order to revise the product. To build a product, all requirements’ uncertainties have to be resolved in some way to finally build a product, but the goal is to not resolve an uncertainty prematurely or for all time.

A key focus suggested in a proposed roadmap for improving software producibility was bridging the conceptual gap between customers and product developers, based on recognizing that there are alternative ways of expressing any problem and many potential solutions that can result (Campbell, 2008). With this perspective, no specific expression of requirements is the “right” one; rather different expressions may be suitable for different purposes. However, underlying all valid expressions are a set of assumptions about certainty, which aspects of needs and associated potential solutions are intrinsic and fixed and which are tradable and changeable. In product lines, these assumptions, of commonality and variability, provide a framework in which true certainties provide a framework within which uncertainties are identified as choices that customers and developers must make through an ongoing process of evaluation and refinement over the life of a needed product.

As is true for product lines, a shift to uncertainty-based acquisition does not require major changes in acquisition policy but rather a change in the level at which programs are required to establish binding requirements (Campbell, 2002). These should be at the level of observable mission-enabling capabilities to be achieved through an iterative process of learning and refinement rather than with a premature over-constrained specification of a specific top-down solution to narrowly conceived needs. This will require changes in the practice of acquisition, replacing the illusion of certainty with a process that, by exposing
uncertainties, builds a stronger foundation for the efficient, predictable delivery of correct and effective capabilities needed by customers.

Summary

- Traditional acquisition practice relies on certainty in requirements
- Uncertainty is unavoidable but seen as a weakness to be eliminated
- Ill-founded resolutions of uncertainty provide an illusion of certainty, preempting proper analysis
- Some uncertainty, due to incomplete knowledge or information, can be resolved with due effort
- Some uncertainty, due to diverse and changing needs, requires changeable solutions
Requirements is a *model* of a product

A model exists to answer specific questions:

• What is the product’s purpose and value?
• What behavior does its users need it to exhibit?
• What is the context in which it operates?
• What interfaces does it have with other devices and systems?
• What are constraints on a solution?

Complete answers are possible only with

• The existing as-built product
• Full documentation of the product’s development

An empirical premise

Requirements certainty is always an illusion

• Incomplete knowledge or understanding
• Incomplete or inaccurate information
• Differing experiences and opinions (among subject matter experts or experienced users)
• Inability to envision all implications of a solution
• Needs and technology that change over time

Normal acquirer viewpoint

• Indecision causes delay
• Make decisions – eliminate uncertainties
When is a requirement not certain

- When it is tradeable (conflicts with a higher priority, costs too much, …)
- When it is only a preference (wished for, not essential)
- When it has unacceptable side effects (performance, security, …)
- When the need has since changed

The acquirer’s dilemma

Reactions to finding uncertainties in requirements:

- Indecision and delay (“somebody has to decide”)
- An ill-founded decision, without proper rationale or exposure, for an inferior product and rework
- Acceptance and accommodation
  - Identify and document uncertainties
  - Analyze implied alternatives, tradeoffs, and rationale to reach a substantiated decision
  - Establish unresolvable uncertainties as product variabilities with decision criteria, enabling deferred change at will
Dealing with uncertainty

Uncertainty \( \xrightarrow{\text{Weak}} \) Best “guess”

Better

Investigate

Decision + Rationale

Changeable Decision + Criteria

Sources of uncertainty in requirements

Transient (second order) uncertainty
- Incomplete knowledge or information
- Disagreements among experts or users
- Complex alternatives requiring tradeoff analyses or experimentation

Persistent (first order) uncertainty
- Changing circumstances, capabilities, or expectations across time or place
- Differing needs or preferences of customers having similar needs (a product line)
**Goals for addressing uncertainty**

**Awareness**
- Expose and characterize all uncertainty

**Understanding**
- Analyze alternative resolutions and tradeoffs

**Reduction**
- Eliminate transient uncertainty, minimize persistent uncertainty, document rationale

**Acccommodation**
- Track and manage implications of persistent uncertainty throughout the product life cycle
